

# 93L415A 1024 x 1-Bit Static Random Access Memory

## General Description

The 93L415A is a 1024-bit read write Random Access Memory (RAM), organized 1024 words by one bit. It is designed for high speed cache, control and buffer storage applications. The device includes full on-chip decoding, separate Data input and non-Inverting Data output, as well as an active LOW Chip Select line.

## Features

- New design to replace old 93415/93L415
- Improved ESD thresholds
- Alpha hard without die coat
- Commercial address access time 93L415A 25 ns max
- Features open collector output
- Power dissipation decreases with increasing temperature

**Functional Description**

The 93L415A is a fully decoded 1024-bit read/write Random Access Memory organized 1024 words by one bit. Bit selection is achieved by means of a 10-bit address A0 through A9.

One Chip Select input is provided for easy memory array expansion of up to 2048 bits without the need for external decoding. For larger memories, the fast chip select access time permits direct address decoding without an increase in overall memory access time.

The read and write functions of the 93L415A are controlled by the state of the active low chip select (CS) input. The write function is controlled by the active low write enable (WE) input. With CS held low and WE held low, the data (D) is written into the memory location specified by addresses

(A0 through A9). To assure a valid write, data setup (t<sub>WSD</sub>), address setup (t<sub>WSA</sub>), data hold (t<sub>WHD</sub>), and address hold (t<sub>WHA</sub>) times must be met. When WE is held HIGH and the chip selected, data is read from the addressed location and presented at the output O.

An open collector output is provided to allow maximum flexibility in output connection. In many applications such as memory expansion, the outputs of many 93L415As can be tied together. In other applications the wired-OR is not used. In either case an external pull-up resistor of R<sub>L</sub> value must be used to provide a HIGH at the output when the chip is deselected. Any R<sub>L</sub> value within the range specified below may be used.

$$\frac{V_{CC}(\text{Max})}{I_{OL} - FO(1.6)} \leq R_L \leq \frac{V_{CC}(\text{Min}) - V_{OH}}{n(I_{CEX}) + FO(0.04)}$$

R<sub>L</sub> is in kΩ

- n = number of wired-OR outputs tied together
- FO = number of TTL Unit Loads (UL) driven
- I<sub>CEX</sub> = Memory Output Leakage Current
- V<sub>OH</sub> = Required Output HIGH Level at Output Node
- I<sub>OL</sub> = Output LOW Current

The minimum R<sub>L</sub> value is limited by the output current sinking ability. The maximum R<sub>L</sub> value is determined by the output and input leakage current which must be supplied to hold the output at V<sub>OH</sub>.

One Unit Load = 40 μA HIGH/1.6 mA LOW.

FO<sub>MAX</sub> = 5 UL.
